

# Zero-Knowledge Proofs of Knowledge

Yehuda Lindell

Bar-Ilan University

Center for Research in Applied  
Cryptography and Cyber Security

# Knowledge – Motivation

- Prove that you know the shortest path from A to B
  - A shortest path exists, but who says that you know it?
- Prove identity:
  - For public key  $h = g^x$  in a group where discrete log is hard, prove that I know  $x$
  - This proves identity since it is my private key and only I know it
  - Attempt: prove in ZK that  $h \in L$  for  $L = \{h \mid \exists x: g^x = h\}$
  - Problem:
    - This statement is TRUE for all group elements (and so ZK is actually trivial – send YES)
    - Who says that I need to know a witness to prove a true statement

# What is Knowledge?

- **Definition:** a student knows the material if she can output it
  - We approximate this by saying that a student knows the material if she can output the answers to the questions on the test
- **Definition:** a machine knows something if it can output it
  - Let  $R$  be an NP-relation
  - A machine knows the witness to a statement  $x$  if it can output  $w$  s.t.  $(x, w) \in R$
- What does it mean for a machine to be able to output it?

# Formalizing Knowledge (first attempt)

- Attempt 1: a machine  $M$  knows the witness to a statement  $x$  if there exists some  $M'$  who outputs  $w$  s.t.  $(x, w) \in R$
- Questions:
  - How does this relate to the machine's actions (e.g., proving a proof)?
  - How is  $M'$  related to  $M$ ; if there is no connection then why does  $M$  know it?

# Formalizing Knowledge (second attempt)

- Attempt 2:
  - We define a PPT oracle machine  $K$ , called a knowledge extractor
  - We say that  $M$  knows the witness to a statement  $x$  if  $K^{M(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$ 
    - $K$  interacts with  $M$  and can use whatever it does to obtain  $w$
    - Since  $K$  is generic, its ability to output  $w$  means that  $M$  knows  $w$
- Questions:
  - This still doesn't relate to the machine's actions (e.g., proving a proof)?
  - $K$  could still just know  $w$  independently of  $M$

# Formalizing Knowledge (third attempt)

- **Definition:**

- We define a PPT oracle machine  $K$ , called a knowledge extractor
- We say that a prover  $P^*$  knows the witness to a statement  $x$  if  $K^{P^*(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$  whenever  $P^*$  convinces  $V$  of  $x$

- **Intuition:**

- $K$  is generic and works for any  $x$  and any  $P^*$ : if  $P^*$  can convince  $V$  then  $K$  can output  $w$  and so  $M$  knows  $w$

- **Question:** what does it mean: “whenever  $P^*$  convinces  $V$  of  $x$ ”?

- $K$  should run in (expected) polynomial-time and output a witness  $w$  with the same probability that  $P^*$  convinces  $V$  of  $x$

# Formalizing Knowledge (final)

- One can always prove in ZK without knowing, with negligible prob
  - Run the zero-knowledge simulator and hope that the verifier's queries in the result match the real queries
- The definition is updated to allow a **knowledge error**  $\kappa$ , which takes this into account
  - If  $P^*$  convinces  $V$  of  $x$  with probability  $> \kappa$ , then  $K$  should run in (expected) polynomial-time and output a witness  $w$  with probability at most  $\kappa$  less than  $P^*$  convinces  $V$  of  $x$
- This property is called **knowledge soundness**

# The Definition

- **Definition (knowledge soundness):**
  - A proof system has **knowledge soundness** with error  $\kappa$  if there exists a PPT  $K$  s.t. for every prover  $P^*$ , if  $P^*$  convinces  $V$  of  $x$  with probability  $\epsilon > \kappa$ , then  $K^{P^*(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$  with probability at least  $\epsilon(|x|) - \kappa(|x|)$

# An Alternative Formulation

- **Motivation:** one can trade off running time and success probability
  - Definition says: run in PPT and output w.p.  $\epsilon$
  - Alternative definition: run in **expected** time  $\frac{1}{\epsilon}$  and always output
- **Definition (knowledge soundness):**
  - A proof system has **knowledge soundness** with error  $\kappa$  if there exists a  $K$  s.t. for every prover  $P^*$ , if  $P^*$  convinces  $V$  of  $x$  with probability  $\epsilon > \kappa$ , then

$K^{P^*(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$  in expected time  $\frac{\text{poly}(|x|)}{\epsilon(|x|) - \kappa(|x|)}$

# Equivalence of the Definitions

- **Original implies alternative:**

- We are given  $K$  that runs in PPT and outputs a witness w.p.  $\epsilon$
- We can run  $K$  many times until a witness is output
  - Since it is an **NP relation**, can verify when get correct result
  - Expected number of times needed is  $1/\epsilon$

- **Alternative implies original:**

- We are given  $K$  that runs in time  $1/\epsilon$  and outputs a witness
- For  $i = 1, \dots, n$ , run  $K$  for  $2^{i+1}$  steps; if finish output witness; else proceed w.p.  $\frac{1}{2}$ 
  - Let  $i$  be smallest s.t.  $2^{i+1} > 1/\epsilon$ : probability of getting here is at least  $2^{-(i+1)} > \epsilon$
  - Expected running time is  $\text{poly}(|x|)$

# Definition of ZKPOK

- **A proof system is a zero-knowledge proof of knowledge if it has**
  - **Completeness:** honest prover convinces honest verifier
  - **Zero knowledge:** ensures verifier learns nothing
  - **Knowledge soundness:** ensures prover knows witness
- **Zero knowledge is a property of the prover**
  - Prover behavior is guaranteed to reveal nothing
  - Protect against a cheating verifier
- **Knowledge soundness is a property of the verifier**
  - Verifier behavior guarantees that prover knows witness
  - Protect against a cheating prover

# Reducing Knowledge Error

- **Sequential composition reduces knowledge error exponentially**
- **Exponentially small error = zero error**
  - Assume knowledge error  $\kappa < 2^{-|x|}$  and consider alternative definition
  - Run  $K^{P^*(\cdot)}(x)$  in parallel to running a brute-force search on witness
    - Assume brute force in time  $2^{|x|}$
  - Let  $P^*$  be s.t. it convinces  $V$  of  $x$  with probability  $\epsilon$ 
    - If  $\epsilon > 2 \cdot \kappa$  then  $\frac{poly(|x|)}{\epsilon - \kappa} < \frac{2 \cdot poly(|x|)}{\epsilon}$  and so succeed in time  $\frac{poly'(|x|)}{\epsilon}$
    - If  $\epsilon < 2 \cdot \kappa$  then  $\frac{poly(|x|)}{\epsilon} > 2^{|x|} \cdot poly(|x|)$  and so brute force finishes

# Constructing ZKPOKs

A Zero-Knowledge proof for  $QR_N$

$$x = w^2 \bmod N$$

**P**

$$x \in QR_N$$

**V**

$$r \in_R \mathbb{Z}_N^*$$

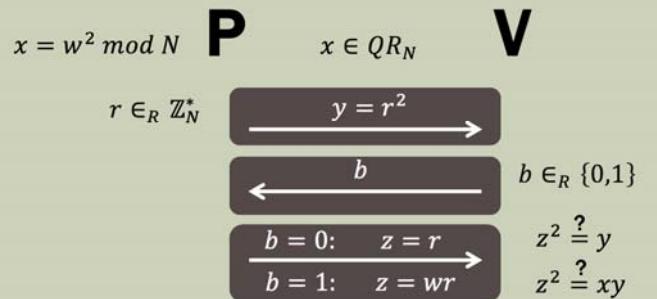

$$y = r^2$$

$$b \in_R \{0,1\}$$

$$\frac{b = 0: \quad z = r}{b = 1: \quad z = wr}$$

$$z^2 \stackrel{?}{=} y$$

$$z^2 \stackrel{?}{=} xy$$

# Knowledge Extraction Idea

- $K$  invokes  $P^*$  and “receives” some  $y$
- $K$  “sends”  $P^*$  the query  $b = 0$  and receives  $z_0$
- $K$  **rewinds** and “sends”  $P^*$  the query  $b = 1$  and receives  $z_1$
- $K$  outputs  $w = \frac{z_1}{z_0} \bmod N$
- **Proof:**
  - If  $P^*$  convinces w.p. greater than  $\kappa = \frac{1}{2}$  then  $(z_0)^2 = y$  and  $(z_1)^2 = xy$ 
    - I am assuming for deterministic  $P^*$ ; to discuss!
  - Thus  $w^2 = \left(\frac{z_1}{z_0}\right)^2 = \frac{xy}{y} = x$  and so  $K$  outputs a square root

# ZKPOK for NP

An interactive proof for  $HAM$

Ham cycle  $w$  **P**  $G \in HAM$  **V**

$\pi \in_R S_n$

$c = Com(\pi(G))$

$b$

$b \in_R \{0,1\}$

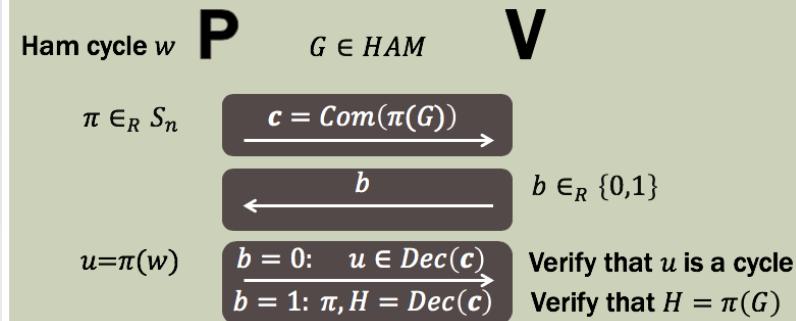

$u = \pi(w)$

$b = 0: u \in Dec(c)$   
 $b = 1: \pi, H = Dec(c)$

Verify that  $u$  is a cycle  
Verify that  $H = \pi(G)$

# ZKPOK for NP

An interactive proof for  $HAM$

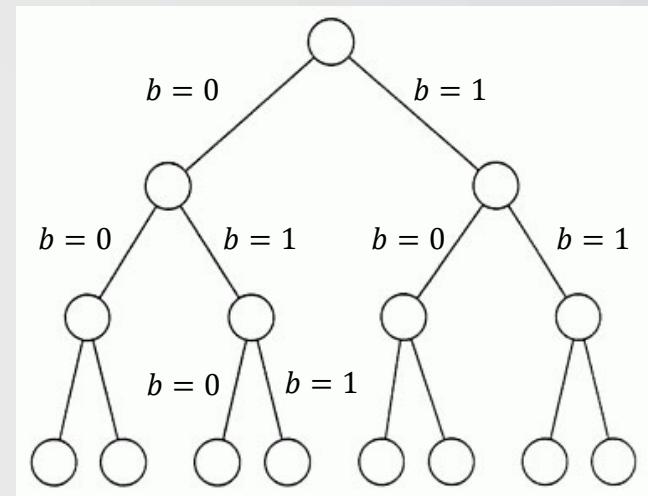

- $K$  invokes  $P^*$  and receives a commitment  $c$
- $K$  sends  $P^*$  the query  $b = 0$  and receives a cycle  $w$
- $K$  rewinds and sends  $P^*$  the query  $b = 1$  and receives  $\pi, \tilde{G}$

## • Proof:

- If  $P^*$  convinces w.p. greater than  $\kappa = \frac{1}{2}$  then  $w$  is a cycle in  $\tilde{G} = \pi(G)$
- Thus,  $\pi^{-1}(w)$  is a Hamiltonian cycle in  $G$

# ZKPOK for NP with Negligible Error

- Run Hamiltonicity  $n = |x|$  times sequentially
- Extractor strategy:
  - Consider binary tree of execution
  - Attempt to extract in  $i$ th execution
    - If  $P^*$  answers both queries, get Hamiltonian cycle
    - If  $P^*$  answers neither query,  $V$  always rejects
    - If  $P^*$  answers exactly one query, go down that edge
  - Repeat with next execution
- Extraction fails iff  $P^*$  answers **exactly one** query in each execution
- Thus, extraction works with probability 1 if  $\epsilon > 2^{-n}$

# Strong Proofs of Knowledge

- **Definition – strong knowledge soundness**
  - A proof system has **strong knowledge soundness** if there exists a negligible function  $\mu$  and a PPT  $K$  s.t. for every prover  $P^*$ , if  $P^*$  convinces  $V$  of  $x$  with probability  $\epsilon > \mu$ , then  $K^{P^*(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$  with probability at least  $1 - \mu(|x|)$
- **Theorem:** sequential Hamiltonicity is a strong proof of knowledge

# Using the Alternative Definition

- **Definition (knowledge soundness):**
  - A proof system has **knowledge soundness** with error  $\kappa$  if there exists a  $K$  s.t. for every prover  $P^*$ , if  $P^*$  convinces  $V$  of  $x$  with probability  $\epsilon > \kappa$ , then  $K^{P^*(\cdot)}(x)$  outputs  $w$  s.t.  $(x, w) \in R$  in expected time  $\frac{\text{poly}(|x|)}{\epsilon(|x|) - \kappa(|x|)}$
- What does it help to run in time  $\frac{\text{poly}(|x|)}{\epsilon(|x|)}$  when this may not be polynomial time?

# Using the Alternative Definition

- **A classic use of zero-knowledge proofs of knowledge:**
  - Within a protocol, prover proves the proof
  - To prove security, a simulator (or reduction) needs the witness
    - Unless verifier would reject, in which case it doesn't matter
- **Using ZKPOKs in proofs of security – simulator (or reduction) plays verifier with prover:**
  - If the verifier rejects, then the simulator can halt, since a real verifier would
  - If the verifier accepts, then the simulator now has to extract the witness

# ZKPOK Inside a Protocol

- **Recall simulator (reduction) strategy:**
  - Verify, then halt if reject and extract if accept
- What is the expected running time of this simulator (reduction)?
  - Probability that prover convinces verifier is  $\epsilon(|x|)$
  - Assuming that the knowledge error  $\kappa$  is 0:
$$E[\text{Time}] = (1 - \epsilon(|x|)) \cdot \text{poly}(|x|) + \epsilon(|x|) \cdot \frac{\text{poly}(|x|)}{\epsilon(|x|)} = \text{poly}(|x|)$$
  - Assuming that the knowledge error  $\kappa$  is negligible:
$$E[\text{Time}] = (1 - \epsilon(|x|)) \cdot \text{poly}(|x|) + \epsilon(|x|) \cdot \frac{\text{poly}(|x|)}{\epsilon(|x|) - \kappa(|x|)} = \text{poly}(|x|) + \frac{\epsilon(|x|)}{\epsilon(|x|) - \kappa(|x|)}$$
  - Actually not polynomial, but can be fixed...

# ZKPOK in a Protocol

- **The issue that arises is that need to both**
  - Simulate the view of the prover in the execution, **and**
  - Extract a witness
- This is called “**witness-extended emulation**”
- A witness-extended emulator  $E^{P^*(\cdot)}(x)$  outputs a **VIEW** and some  $w$ :
  - The view output is indistinguishable from a real execution
  - The probability that the view is accepting and yet  $(x, w) \notin R$  is negligible
  - $E$  runs in expected polynomial-time

# Witness-Extended Emulation

- **Lemma:** If  $(P, V)$  is a ZKPOK, then there exists a witness extended emulator for  $(P, V)$ .
  - Very useful when use ZKPOK inside proofs of security (and greatly simplifies)
- Can also formalize an ideal ZK functionality:
$$\mathcal{F}_{\text{zk}}((x, w), x) = (\lambda, R(x, w))$$
- **Lemma:** If  $(P, V)$  is a ZKPOK, then it securely computes the ideal ZK functionality (in the secure computation sense).

# Other Applications

- A zero-knowledge proof for  $NQR_N$
- Non-oblivious encryption
- Prove that committed value has a property, for statistically hiding
- Identification schemes

# A zero-knowledge proof for $\overline{QR}_N$

Interactive proof for  $\overline{QR}_N$  [GMR'85]

**P**

$x \notin QR_N$

**V**

$$\frac{z = y^2 \quad b = 0}{z = xy^2 \quad b = 1}$$

$$\begin{aligned} b &\in_R \{0,1\} \\ y &\in_R \mathbb{Z}_N^* \end{aligned}$$

$$\frac{b'(z) = 0 \quad z \in QR_N}{b'(z) = 1 \quad z \notin QR_N}$$

$$b' \stackrel{?}{=} b$$

# A ZK proof for $\overline{QR}_N$

- **Why is the proof not ZK?**

- The verifier may have some  $z$  and wants to know if is QR or not

- **How can we make this proof ZK?**

- The verifier sends  $z$  and proves that it **knows**  $y$  s.t.  $z = xy$  or  $z = xy^2$

- **Why is ZK not enough and why is a ZKPOK needed?**

- Intuitively: for every  $z$ , there exists a  $y$  s.t.  $z = xy$  or  $z = xy^2$ , so statement is always true
- Formally: simulation strategy

Interactive proof for  $\overline{QR}_N$  [GMR'85]

**P**       $x \notin QR_N$       **V**

$$\xleftarrow{\quad z = y^2 \quad \quad b = 0 \quad} \quad \xrightarrow{\quad z = xy^2 \quad \quad b = 1 \quad}$$

$$\begin{aligned} b \in_R \{0,1\} \\ y \in_R \mathbb{Z}_N^* \end{aligned}$$

$$\frac{b'(z) = 0 \quad z \in QR_N}{b'(z) = 1 \quad z \notin QR_N} \quad \xrightarrow{\quad b' \stackrel{?}{=} b \quad}$$

$$b' \stackrel{?}{=} b$$

# A ZK proof for $\overline{QR}_N$

- **Simulation Strategy**

- Simulator  $S$  runs  $V^*$  and gets  $z$
- Simulator doesn't know whether it should answer  $b = 0$  or  $b = 1$
- Simulator runs the **knowledge extractor** on the proof from  $V^*$  and gets  $y$
- Simulator checks if  $z = xy$  or  $z = xy^2$ , and so knows if  $b = 0$  or  $b = 1$

Interactive proof for  $\overline{QR}_N$  [GMR'85]

**P**  $x \notin QR_N$  **V**

$$\xleftarrow{\begin{array}{ll} z = y^2 & b = 0 \\ z = xy^2 & b = 1 \end{array}} \quad \begin{array}{l} b \in_R \{0,1\} \\ y \in_R \mathbb{Z}_N^* \end{array}$$

$$\xrightarrow{\begin{array}{ll} b'(z) = 0 & z \in QR_N \\ b'(z) = 1 & z \notin QR_N \end{array}} \quad b' \stackrel{?}{=} b$$

# Non-Oblivious Encryption

- Provide an encryption and prove that you know what's encrypted
- Motivation:
  - Prevent copying (e.g., in auction)
  - Guarantee non-malleability (did not take a previous ciphertext and maul)

# Prove Property of Statistical Committed Value

- Consider a statistically-hiding commitment scheme
  - A commitment value  $c$  can be a commitment to any message
- Committer wishes to prove that it committed to a value in a certain range (or any other property)
- Statement is almost always true for any given  $c$
- The question is whether the committer **knows** a decommitment to a message with this property
- **Rule:** whenever ZK is used with statistical hiding, ZKPOK is needed

# Identification Schemes

- Alice has a public key  $h = g^x$
- In order to authenticate, she proves that she knows the dlog of  $h$
- This must be a ZKPOK, since ZK for the language of DLOG is trivial
